

Web Scrapping Bonus Question

Q2.

To scrape through a limit of records we need to know how many records are displayed in one page view.

1. Currently there are 10 records per page. So as per the limit set, we define how many pages we must loop through to reach the required limit of the records.
2. Hence we gather all the page source and click on Next on every page load until the loop count is done
3. On every page load , we gather all the information required
4. We also check if the Expand_review is set True, we have to expand the read_more option for every review and get all the description per review
5. We will have to click on Next button on every page load.
6. If the limit of records is reached we break out of the loop and convert all the gathered information to Data frame and return.
